Abstract
Infectious diseases remain one of the most important public health challenges worldwide. Their spread poses a significant threat to public health, particularly among children, older adults, and individuals with weakened immune systems. The prevention of infectious diseases involves a comprehensive set of sanitary, hygienic, epidemiological, immunological, and organizational measures aimed at preventing the occurrence and transmission of infections. Vaccination, personal hygiene, access to safe drinking water, sanitary education, and early detection of infectious diseases play particularly important roles in reducing the incidence of infections.

Keywords: infectious diseases, prevention, vaccination, epidemiology, immunity, personal hygiene, disinfection, infection control, public health.

Relevance of the Study. Infectious diseases remain one of the most significant medical and social problems worldwide. Despite advances in modern medicine, improvements in diagnostic methods, and the development of new medications, infectious diseases continue to have a considerable impact on morbidity and mortality rates.

The main factors contributing to the spread of infections include inadequate personal hygiene, unfavorable sanitary conditions, environmental pollution, insufficient vaccination coverage, and violations of infection prevention and control protocols.

Particular attention should be paid to the prevention of healthcare-associated infections and the spread of antimicrobial-resistant microorganisms. The World Health Organization recognizes infection prevention and control as essential components of patient safety and healthcare quality.

Aim of the Study. To investigate the main methods of infectious disease prevention and determine the role of sanitary and hygienic measures, vaccination, and infection control in reducing the prevalence of infectious diseases among the population.

Objectives of the Study. To study the main routes of transmission of infectious diseases. To examine modern methods of specific and nonspecific prevention. To determine the importance of vaccination in preventing infectious diseases. To assess the role of personal and public hygiene in preventing the spread of infections. To investigate the importance of disinfection, sterilization, and sanitary-epidemiological surveillance. To develop preventive recommendations aimed at improving public awareness of infectious diseases.

Materials and Methods. The study is based on the analysis and review of scientific literature, comparative analysis of modern approaches to infectious disease prevention, and examination of recommendations issued by the World Health Organization and established principles of infection prevention and control.
Particular attention was given to the mechanisms of infection transmission, the effectiveness of preventive measures, and the role of healthcare professionals in preventing the spread of infectious agents.

Results of the Study. The analysis of scientific literature demonstrates that infectious disease prevention should be implemented comprehensively and include several major areas.
Specific Prevention. Vaccination is the primary method of specific prevention. The administration of vaccines stimulates the development of specific immunity and reduces the risk of severe infectious diseases. Immunization plays an essential role in preventing measles, poliomyelitis, diphtheria, pertussis, hepatitis B, and other vaccine-preventable diseases.
Nonspecific Prevention. The main nonspecific preventive measures include: Regular handwashing with soap and water. Observance of personal hygiene rules.

Consumption of safe drinking water. Proper heat treatment of food products. Regular ventilation of indoor spaces. Use of personal protective equipment when necessary. Avoidance of close contact with individuals showing symptoms of contagious diseases.

Sanitary and Epidemiological Measures. Important preventive measures include the early identification of infected individuals, isolation when epidemiologically indicated, medical monitoring of exposed individuals, disinfection, and sanitary monitoring of environmental objects.

Prevention of Infections in Healthcare Facilities. Particular attention should be paid to compliance with the principles of asepsis and antisepsis, proper sterilization of medical instruments, safe injection practices, the use of personal protective equipment, and regular monitoring of sanitary and infection control procedures.

Rational Use of Antibacterial Drugs. The inappropriate use of antibiotics contributes to the development of antimicrobial resistance. Therefore, antibacterial medications should be prescribed by qualified healthcare professionals according to appropriate clinical indications. Effective infection prevention reduces the need for antibiotic treatment and helps limit the spread of resistant microorganisms.

Conclusion

The prevention of infectious diseases is one of the most important priorities of public healthcare. The comprehensive implementation of vaccination, sanitary and hygienic measures, disinfection, early diagnosis, and infection prevention and control can significantly reduce the risk of the occurrence and spread of infectious diseases.

Improving public health literacy and promoting responsible attitudes toward personal health are particularly important. Effective preventive strategies require cooperation between healthcare professionals, educational institutions, government organizations, and the general population.
